Abstract

We use the Lagrange-Bürmann inversion theorem to characterize the generating function of the central coefficients of the elements of the Riordan group of matrices. We apply this result to calculate the generating function of the central elements of a number of explicit Riordan arrays, defined by rational expressions, and in two cases we use the generating functions thus found to calculate the Hankel transforms of the central elements, which are themselves expressible as combinatorial polynomials. We finally look at two cases of Riordan arrays defined by non-rational expressions. The last example uses our methods to calculate the generating function of $\binom{3n}{n}$.

1 Introduction

The central coefficients of many common (ordinary) Riordan arrays play an important role in combinatorics. For instance, the central terms of the Pascal triangle, defined by the Riordan array $\left(\frac{1}{1-t}, \frac{t}{1-t}\right)$, are the central binomial coefficients $\binom{2n}{n}$ [A000984](#), with a multitude of combinatorial interpretations. Similarly, the central elements of the Delannoy triangle, $\left(\frac{1}{1-t}, \frac{t(1+t)}{1-t}\right)$ are the central Delannoy numbers $\sum_{k=0}^n \binom{n}{k}^2 2^k$ [A001850](#), again with many combinatorial interpretations. It is interesting therefore to be able to give the generating function of such central terms in a systematic way. In two recent papers [\[2, 6\]](#), it has been shown how to find the generating function of the central elements of elements of the Bell subgroup of the Riordan group. For instance, the Pascal triangle $\left(\frac{1}{1-t}, \frac{t}{1-t}\right)$ is an element of this subgroup. In this note, we shall extend this result to arbitrary elements of the Riordan group. We first recall the result concerning the Bell subgroup that we wish to extend. We use the notation $\bar{f}(t)$ to denote the compositional inverse of the power series f (where $f(0) = 0$). This is the unique function such that $f(\bar{f}(t)) = \bar{f}(f(t)) = t$.

Theorem 1.1. *Let $(d(t), td(t))$ be an element of the Bell subgroup of the Riordan group of matrices \mathcal{R} . If $d_{n,k}$ denotes the (n, k) -th element of this matrix, then we have*

$$d_{2n,n} = (n+1)[t^n] \frac{1}{t} \overline{\left(\frac{t}{d(t)}\right)}(t).$$

Corollary 1.2. If $d_{n,k}$ denotes the general term of the Bell matrix $(d(t), td(t))$, then the generating function of the central terms $d_{2n,n}$ is given by

$$\frac{d}{dt} \overline{\left(\frac{t}{d(t)} \right)}.$$

Example 1.3. The most well-known example of a Bell matrix (see later) is the Binomial matrix \mathbf{B} with general element $d_{n,k} = \binom{n}{k}$. As a member of the Riordan group of matrices, this is

$$\mathbf{B} = \left(\frac{1}{1-t}, \frac{t}{1-t} \right).$$

Then the generating function of $d_{2n,n} = \binom{2n}{n}$ is given by

$$\frac{d}{dt} \overline{t(1-t)} = \frac{d}{dt} \frac{1 - \sqrt{1-4t}}{2} = \frac{1}{\sqrt{1-4t}}.$$

The next section provides a brief review of integer sequences, the Lagrange-Bürmann inversion theorem, and Riordan arrays, and may be skipped by those familiar with these notions. We then announce and prove our general result, and finally we look at some examples.

Many interesting examples of sequences and Riordan arrays can be found in Neil Sloane's On-Line Encyclopedia of Integer Sequences (OEIS), [12, 13]. Sequences are frequently referred to by their *Ann* OEIS number.

2 Integer sequences, Lagrange Inversion and Riordan arrays

For an integer sequence a_n , that is, an element of $\mathbb{Z}^{\mathbb{N}}$, the power series $f(t) = \sum_{k=0}^{\infty} a_k t^k$ is called the *ordinary generating function* or g.f. of the sequence. a_n is thus the coefficient of t^n in this series. We denote this by $a_n = [t^n]f(t)$. For instance, $F_n = [t^n] \frac{t}{1-t-t^2}$ is the n -th Fibonacci number [A000045](#), while $C_n = [t^n] \frac{1-\sqrt{1-4t}}{2t}$ is the n -th Catalan number [A000108](#). The properties and examples of use of the notation $[t^n]$ can be found in [9].

For a power series $f(t) = \sum_{n=0}^{\infty} a_n t^n$ with $f(0) = 0$ and $f'(0) \neq 0$ we define the *reversion* or *compositional inverse* of f to be the power series $\bar{f}(t)$ (also written as $f^{[-1]}(t)$) such that $f(\bar{f}(t)) = t$. We sometimes write $\bar{f} = \text{Rev}f$.

The following is the version of Lagrange inversion that we shall need [8, 15].

Theorem 2.1. (*Lagrange-Bürmann Inversion*). Suppose that a formal power series $w = w(t)$ is implicitly defined by the relation $w = t\phi(w)$, where $\phi(t)$ is a formal power series such that $\phi(0) \neq 0$. Then, for any formal power series $F(t)$,

$$[t^n]F(w(t)) = \frac{1}{n} [t^{n-1}]F'(t)(\phi(t))^n.$$

In the sequel, we shall be interested in the Hankel transform of the central terms that we shall meet. The Hankel transform [5, 7] of a sequence a_n is the sequence h_n where $h_n = |a_{i+j}|_{0 \leq i, j \leq n}$. If the g.f. of a_n is expressible as a continued fraction of the form

$$\frac{\mu_0}{1 - \alpha_0 t - \frac{\beta_1 t^2}{1 - \alpha_1 t - \frac{\beta_2 t^2}{1 - \alpha_2 t - \frac{\beta_3 t^2}{1 - \alpha_3 t - \dots}}}},$$

then the Hankel transform of a_n is given by [5]

$$h_n = \mu_0^{n+1} \beta_1^n \beta_2^{n-1} \dots \beta_{n-1}^2 \beta_n.$$

The *Riordan group* [3, 11, 14], is a set of infinite lower-triangular integer matrices, where each matrix is defined by a pair of generating functions $d(t) = 1 + d_1 t + d_2 t^2 + \dots$ and $h(t) = h_1 t + h_2 t^2 + \dots$ where $h_1 \neq 0$ [14]. The corresponding matrix is the matrix whose i -th column is generated by $d(t)h(t)^i$ (the first column being indexed by 0). The matrix corresponding to the pair d, h is denoted by (d, h) . The group law, which corresponds to matrix multiplication, is then given by

$$(d, h) \cdot (f, g) = (d, h)(f, g) = (d(f \circ h), g \circ h).$$

The identity for this law is $I = (1, t)$ and the inverse of (d, h) is

$$(d, h)^{-1} = (1/(d \circ \bar{h}), \bar{h}),$$

where \bar{h} is the compositional inverse of h . We denote by \mathcal{R} the group of Riordan matrices. If \mathbf{M} is the matrix (d, h) , and $\mathbf{a} = (a_0, a_1, \dots)^T$ is an integer sequence with ordinary generating function $\mathcal{A}(t)$, then the sequence $\mathbf{M}\mathbf{a}$ has ordinary generating function $d(t)\mathcal{A}(h(t))$. The (infinite) matrix (d, h) can thus be considered to act on the ring of integer sequences $\mathbb{Z}^{\mathbb{N}}$ by multiplication, where a sequence is regarded as a (infinite) column vector. We can extend this action to the ring of power series $\mathbb{Z}[[t]]$ by

$$(d, h) : \mathcal{A}(t) \mapsto (d, h) \cdot \mathcal{A}(t) = d(t)\mathcal{A}(h(t)).$$

Example 2.2. The so-called *binomial matrix* \mathbf{B} [A007318](#) is the element $(\frac{1}{1-t}, \frac{t}{1-t})$ of the Riordan group. It has general element $\binom{n}{k}$, and hence as an array coincides with Pascal's triangle. More generally, \mathbf{B}^m is the element $(\frac{1}{1-mt}, \frac{t}{1-mt})$ of the Riordan group, with general term $\binom{n}{k} m^{n-k}$. We find that the inverse \mathbf{B}^{-m} of \mathbf{B}^m is given by $(\frac{1}{1+mt}, \frac{t}{1+mt})$.

The *Bell* subgroup of \mathcal{R} is the set of matrices of the form

$$(d(t), td(t)).$$

Note that

$$(d(t), td(t))^{-1} = \left(\frac{\overline{td}}{t}, \overline{td} \right).$$

An interesting sequence characterization of Bell matrices may be found in [4].

3 The main result

The main result of this note is the following.

Theorem 3.1. *Let $(d(t), h(t)) = (d(t), tf(t))$ be an element of the Riordan group of matrices \mathcal{R} (with $f(0) \neq 0$). Let $d_{n,k}$ denote the (n, k) -th element of this matrix, and let $v(t)$ denote the power series (with $v(0) = 0$)*

$$v(t) = \overline{\left(\frac{t}{f(t)}\right)}.$$

Then the generating function of the central term sequence $d_{2n,n}$ is given by

$$\frac{d(v(t))}{f(v(t))} \frac{d}{dt} v(t).$$

Proof. We let $d_{n,k}$ denote the general element of the Riordan array $(d(t), tf(t))$. Then we have

$$\begin{aligned} d_{2n,n} &= [t^{2n}]d(t)(tf(t))^n \\ &= [t^{2n}]t^n d(t)f(t)^n \\ &= [t^n] \frac{d(t)}{f(t)} f(t)^{n+1} \\ &= (n+1) \frac{1}{n+1} [t^n] F'(t) f(t)^{n+1}, \end{aligned}$$

where $F'(t) = \frac{d(t)}{f(t)}$. Applying the Lagrange-Bürmann inversion theorem, we obtain

$$\begin{aligned} d_{2n,n} &= (n+1)[t^{n+1}]F(v(t)) \\ &= [t^n]F'(v(t))v'(t) \\ &= [t^n] \frac{d(v(t))}{f(v(t))} \frac{d}{dt} v(t). \end{aligned}$$

□

4 Examples

Example 4.1. We look at the matrix

$$\left(\frac{1}{1-2t}, \frac{t(1-2t)}{1-3t}\right).$$

The central elements of this matrix begin 1, 3, 15, 90, 579, 3858, ... In this case, we have

$$v(t) = \overline{\left(\frac{t}{f(t)}\right)} = \overline{\left(\frac{t(1-3t)}{1-2t}\right)}.$$

Thus $v(t)$ is the appropriate solution (with $v(0) = 0$) of the equation

$$\frac{v(1-3v)}{1-2v} = t.$$

We find that

$$v(t) = \frac{1+2t - \sqrt{1-8t+4t^2}}{6}.$$

We also have that

$$\frac{d(t)}{f(t)} = \frac{1-3t}{(1-2t)^2}.$$

The generating function of $d_{2n,n}$ is thus given by

$$\frac{g(v(t))}{f(v(t))} \frac{d}{dt} v(t) = \frac{1+4t + \sqrt{1-8t+4t^2}}{2\sqrt{1-8t+4t^2}}.$$

We can generalize this result to the case of the Riordan array

$$\left(\frac{1}{1-rt}, \frac{t(1-rt)}{1-(r+1)t} \right).$$

We find in this case that the central term sequence $d_{2n,n}$ is generated by

$$\frac{1+rt + \sqrt{1-2(r+2)t+r^2t^2}}{2\sqrt{1-2(r+2)t+r^2t^2}}.$$

The general element of $\left(\frac{1}{1-rt}, \frac{t(1-rt)}{1-(r+1)t} \right)$ is given by

$$d_{n,k} = [t^n] \frac{1}{1-rt} \left(\frac{t(1-rt)}{1-(r+1)t} \right)^k,$$

which gives us the expression

$$d_{2n,n} = \sum_{k=0}^n \binom{n-1}{k} \binom{2n-k-1}{n-k} (-r)^k (r+1)^{n-k}.$$

The bivariate generating function

$$\frac{1+rt + \sqrt{1-2(y+2)t+y^2t^2}}{2\sqrt{1-2(y+2)t+y^2t^2}}$$

is the generating function of the lower-triangular matrix with general element

$$\binom{n}{k} \binom{2n-k-1}{n-k},$$

and so we also have

$$d_{2n,n} = \sum_{k=0}^n \binom{n}{k} \binom{2n-k-1}{n-k} r^k.$$

We note that this matrix begins

$$\begin{pmatrix} 1 & 0 & 0 & 0 & \cdots \\ 1 & 1 & 0 & 0 & \cdots \\ 3 & 4 & 1 & 0 & \cdots \\ 10 & 18 & 9 & 1 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

We finish this example by offering the following conjecture for the form of the Hankel transform h_n of $d_{2n,n}$ [7].

$$h_n = (r+1)^{\lceil \frac{n^2}{2} \rceil} \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} 4^k r^k \sum_{j=0}^{n-2k} \binom{2k+j+1}{j} \binom{n-j-1}{n-2k-j}.$$

Example 4.2. In this example, we start with the Riordan array

$$\left(\frac{1}{1-2t}, \frac{t(1-3t)}{1-2t} \right).$$

Then

$$\frac{v(1-2v)}{1-3v} = t$$

gives us

$$v(t) = \frac{1-3t - \sqrt{1-14t+9t^2}}{4},$$

while in this case we have

$$\frac{d(t)}{f(t)} = \frac{1}{1+3t}.$$

We obtain that the sequence of central terms $d_{2n,n}$, which begins

$$1, 7, 69, 763, 8881, 106407, 1298949, 16065483, \dots,$$

has generating function

$$\frac{1}{\sqrt{1-14t+9t^2}}.$$

This sequence is [A084774](#). It corresponds to the central coefficients of $(1+7t+10t^2)^n$. We now look at the general case of the matrix

$$\left(\frac{1}{1-rt}, \frac{t(1-(r+1)t)}{1-rt} \right).$$

We obtain

$$v(t) = \frac{1 - (1+r)t - \sqrt{1 - 2(1+3r)t + (r+1)^2t^2}}{2r},$$

and

$$\frac{d(t)}{f(t)} = \frac{1}{1 + (1+r)t}.$$

We find that the central term sequence $d_{2n,n}$ is generated by

$$\frac{1}{\sqrt{1 - 2(3r+1)t + (r+1)^2t^2}}.$$

We can then show [10] that

$$d_{2n,n} = [t^n](1 + (3r+1)t + r(r+1)t^2)^n,$$

and

$$d_{2n,n} = \sum_{k=0}^{\lfloor \frac{n}{2} \rfloor} \binom{n}{2k} \binom{2k}{k} (3r+1)^{n-2k} (r(2r+1))^k.$$

We have

$$\frac{1}{\sqrt{1 - 2(3r+1)t + (r+1)^2t^2}} = \frac{1}{1 - (3r+1)t - \frac{2r(r+1)t^2}{1 - (3r+1)t - \frac{r(r+1)t^2}{1 - (3r+1)t - \dots}}}.$$

This shows that the Hankel transform of $d_{2n,n}$ in this instance is given by

$$h_n = 2^n (r(r+1))^{\binom{n+1}{2}}.$$

Example 4.3. We finish this section by looking at the Pascal-like triangles [1] given by

$$\left(\frac{1}{1-t}, \frac{t(1+rt)}{1-t} \right).$$

We have

$$\frac{v(1-v)}{1+rv} = t,$$

and hence

$$v(t) = \frac{1 - rt + \sqrt{1 - 2(r+2)t + r^2t^2}}{2},$$

and

$$\frac{d(t)}{f(t)} = \frac{1}{1+rt}.$$

We find that the generating function of $d_{2n,n}$ is given by

$$\frac{1}{\sqrt{1 - 2(r+2)t + r^2t^2}},$$

which [10] shows that

$$d_{2n,n} = [t^n](1 + (r + 2)t + (r + 1)t^n)^n,$$

with

$$d_{2n,n} = \sum_{k=0}^n \binom{n}{k} \binom{2n-k}{n} r^k.$$

We have

$$\frac{1}{\sqrt{1 - 2(r + 2)t + r^2t^2}} = \frac{1}{1 - (r + 2)t - \frac{2(r + 1)t^2}{1 - (r + 2)t - \frac{(r + 1)t^2}{1 - (r + 2)t - \dots}}}.$$

This shows that the Hankel transform of $d_{2n,n}$ in this instance is given by

$$h_n = 2^n(r + 1)^{\binom{n+1}{2}}.$$

5 Non-rational terms

In this section, we look at two simple examples of Riordan arrays defined by non-rational terms. In the first, the generating function of the central terms is elementary, while this is not the case for the central elements of the second array.

Example 5.1. We consider the Riordan array

$$\left(\frac{1}{\sqrt{1 - 4t}}, \frac{t}{c(t)} \right),$$

where

$$c(t) = \frac{1 - \sqrt{1 - 4t}}{2t}$$

is the generating function of the Catalan numbers [A000108](#). This matrix begins

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & \dots \\ 2 & 1 & 0 & 0 & 0 & 0 & \dots \\ 6 & 1 & 1 & 0 & 0 & 0 & \dots \\ 20 & 3 & 0 & 1 & 0 & 0 & \dots \\ 70 & 10 & 1 & -1 & 1 & 0 & \dots \\ 252 & 35 & 4 & 0 & -2 & 1 & \dots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

We have

$$vc(v) = t,$$

and hence

$$v(t) = t(1 - t).$$

We have

$$\frac{d(t)}{f(t)} = \frac{1 - \sqrt{1 - 4t}}{2t\sqrt{1 - 4t}}.$$

We find that

$$\frac{d(v(t))}{f(v(t))} = \frac{1}{(1-t)(1-2t)}.$$

But

$$(t(1-t))' = 1 - 2t,$$

and so we find that the generating function of $d_{2n,n}$ in this case is $\frac{1}{1-t}$. Thus the central terms of the Riordan array $\left(\frac{1}{\sqrt{1-4t}}, \frac{t}{c(t)}\right)$ are all equal to 1.

Example 5.2. For this example, we look at the array

$$\left(\frac{1}{\sqrt{1-4t}}, tc(t)\right).$$

This is the matrix [A092392](#) with general element

$$d_{n,k} = \binom{2n-k}{n}.$$

Thus we have

$$d_{2n,n} = \binom{3n}{2n} = \binom{3n}{n},$$

which begins

$$1, 3, 15, 84, 495, 3003, 18564, 116280, \dots$$

This is [A005809](#). Solving the equation

$$\frac{v}{c(v)} = t,$$

we find that

$$v(t) = \frac{2}{\sqrt{3}}\sqrt{t} \sin\left(\frac{1}{3} \arcsin\left(\frac{1}{2}\sqrt{27t}\right)\right).$$

This is the g.f. of the sequence that begins

$$0, 1, 1, 3, 12, 55, 273, 1428, \dots,$$

or the sequence $\frac{1}{2n+1}\binom{3n}{n}$ with a 0 at the beginning. Thus $v'(t)$ is the g.f. of $\frac{n+1}{2n+1}\binom{3n}{n}$, [A174687](#). We have

$$\frac{d(t)}{f(t)} = \frac{1}{\sqrt{1-4t}} \frac{1}{c(t)} = \frac{1 - \sqrt{1-4t}}{2t\sqrt{1-4t}},$$

from which it follows that we have

$$\frac{d(v(t))}{f(v(t))} = \frac{1}{2} \left(1 + \frac{3^{1/4}}{\sqrt{\sqrt{3} - 8\sqrt{t} \sin\left(\frac{1}{3} \arcsin\left(\frac{\sqrt{27t}}{2}\right)\right)}} \right).$$

Thus the generating function of the central elements $\binom{3n}{n}$ of the Riordan array

$$\left(\frac{1}{\sqrt{1-4t}}, tc(t) \right)$$

is given by

$$\frac{1}{\sqrt{3}} \left(1 + \frac{3^{1/4}}{\sqrt{\sqrt{3} - 8\sqrt{t} \sin\left(\frac{1}{3} \arcsin\left(\frac{\sqrt{27t}}{2}\right)\right)}} \right) \frac{d}{dt} \sqrt{t} \sin\left(\frac{1}{3} \arcsin\left(\frac{1}{2}\sqrt{27t}\right)\right).$$

We see that even in the case of this relatively simply defined Riordan array, the generating function of the central terms is far from elementary.
